PARTIAL-ORDER PLANNING

Partial Order Planning

- The answer to the problem we ended the last lecture with is to use partial order planning.
- Basically this gives us a way of checking before adding an action to the plan that it doesn't mess up the rest of the plan.
- The problem is that in this recursive process, we don't know what the rest of the plan is.
- Need a new representation *partially ordered plans*.

Partially ordered plans

- *Partially ordered* collection of steps with
 - *Start* step has the initial state description as its effect
 - *Finish* step has the goal description as its precondition
 - *causal links* from outcome of one step to precondition of another
 - *temporal ordering* between pairs of steps
- *Open condition* = precondition of a step not yet causally linked
- A plan is *complete* iff every precondition is achieved
- A precondition is *achieved* iff it is the effect of an earlier step and no *possibly intervening* step undoes it

Plan construction (2)

Plan construction (3)

cis32-spring2009-parsons-lect16

Planning process

- Operators on partial plans:
 - *add a link* from an existing action to an open condition
 - *add a step* to fulfill an open condition
 - *order* one step wrt another to remove possible conflicts
- Gradually move from incomplete/vague plans to complete, correct plans
- Backtrack if an open condition is unachievable or if a conflict is unresolvable

function POP(*initial*, goal, operators) returns plan $plan \leftarrow MAKE-MINIMAL-PLAN(initial, goal)$ **loop do if** SOLUTION?(*plan*) **then return** *plan* $S_{need}, c \leftarrow SELECT-SUBGOAL($ *plan*)CHOOSE-OPERATOR(*plan*, operators, S_{need}, c) RESOLVE-THREATS(*plan*) **end**

function SELECT-SUBGOAL(*plan*) **returns** *S*_{need}, *c*

```
pick a plan step S_{need} from STEPS(plan)
with a precondition c that has not been achieved
return S_{need}, c
```

cis32-spring2009-parsons-lect16

```
procedure CHOOSE-OPERATOR(plan, operators, S<sub>need</sub>, c)
```

choose a step S_{add} from *operators* or STEPS(*plan*) that has *c* as an effect if there is no such step **then fail** add the causal link $S_{add} \xrightarrow{c} S_{need}$ to LINKS(*plan*) add the ordering constraint $S_{add} \prec S_{need}$ to ORDERINGS(*plan*) if S_{add} is a newly added step from *operators* **then** add S_{add} to STEPS(*plan*) add *Start* \prec $S_{add} \prec$ *Finish* to ORDERINGS(*plan*)

procedure RESOLVE-THREATS(plan)

```
for each S_{threat} that threatens a link S_i \stackrel{c}{\longrightarrow} S_j in LINKS(plan) do
choose either
Demotion: Add S_{threat} \prec S_i to ORDERINGS(plan)
Promotion: Add S_j \prec S_{threat} to ORDERINGS(plan)
if not CONSISTENT(plan) then fail
end
```

Clobbering

• A *clobberer* is a potentially intervening step that destroys the condition achieved by a causal link. E.g., *Go*(*Home*) clobbers *At*(*Supermarket*):

Properties of POP

- Nondeterministic algorithm: backtracks at *choice* points on failure:
 - choice of S_{add} to achieve S_{need}
 - choice of demotion or promotion for clobberer
 - selection of S_{need} is irrevocable
- POP is sound, complete, and *systematic* (no repetition)
- Extensions for disjunction, universals, negation, conditionals
- Can be made efficient with good heuristics derived from problem description
- Particularly good for problems with many loosely related subgoals

Summary

- This lecture has looked at a more advanced approach to planning.
 - Partial order planning
- This requires a new way of looking at the world, but the payoff is a more robust approach.
- We also looked at the POP algorithm, ...
- ... and saw how it could solve the Sussman anomaly.
