

• Note no *visual* or *aural* component to basic Turing test — augmented test involves video & audio feed to entity.

cisc3410-fall2010-parsons-lect01b

• Human interrogates entity via teletype for 5 minutes.

- If, after 5 minutes, human cannot tell whether entity is human or machine, then the entity must be counted as intelligent
- (The guy on the right is Joshua Lederberg, another AI pioneer)

cisc3410-fall2010-parsons-lect01b

Thinking Humanly

- Try to understand how the mind works how do we think?
- Two possible routes to find answers:
 - by *introspection* we figure it out ourselves!
 - by *experiment* draw upon techniques of psychology to conduct controlled experiments. ("Rat in a box"!)
- The discipline of *cognitive science*: particularly influential in *vision, natural language processing,* and *learning*.

cisc3410-fall2010-parsons-lect01b

Thinking Rationally

- Trying to understand how we *actually* think is one route to AI but how about how we *should* think.
- Use *logic* to capture the *laws of rational thought* as *symbols*.
- *Reasoning* involves shifting symbols according to well-defined rules (like algebra).
- Result is *idealised* reasoning.
- Logicist approach is theoretically attractive.

cisc3410-fall2010-parsons-lect01b

cisc3410-fall2010-parsons-lect01b

• Lots of problems:

- *transduction* how to map the environment to symbolic representation;
- *representation* how to represent real world phenomena (time, space, ...) symbolically;
- *reasoning* how to do symbolic manipulation *tractability* so it can be done by real computers!
- We are still a long way from solving these problems.
- In general logic-based approaches are unpopular in AI at the moment.

cisc3410-fall2010-parsons-lect01b

The transduction problem

• How many horses do you see?

• Locating objects in pictures is relatively easy.

• But identifying objects much harder.

cisc3410-fall2010-parsons-lect01b

11

• Achieving *perfect* rationality — making the best decision theoretically possible — is not usually possible, due to *limited resources*:

- limited time;
- limited computational power;
- limited memory;
- limited or uncertain information about environment.
- The trick is to *do the best with what you've got*!
- This is easier than doing perfectly, but still tough.

cisc3410-fall2010-parsons-lect01b

13

15

Early enthusiasm, 1952–69:

14

16

• Major centres established:

Minsky, MIT

McCarthy, Stanford

Newell & Simon, CMU

• For the next 20 years these places dominated the field.

cisc3410-fall2010-parsons-lect01b

Brief History of AI

Gestation, 1943–56:

- McCulloch & Pitts (1943) artificial neural net — proved equivalent to Turing machine;
- Shannon, Turing (1950) chess playing programs
- Marvin Minsky (1951) first neural net computer — SNARC
- Dartmouth College (1956) term "AI" coined by John McCarthy Newell & Simon presented LOGIC THEORIST program

- Lots of progress.
- Programs written that could:
 - plan,
 - learn,
 - play games,
 - prove theorems,
- in general, *solve problems*.
- Major feature of the period were *microworlds* toy problem domains.

Example: blocks world.

cisc3410-fall2010-parsons-lect01b

cisc3410-fall2010-parsons-lect01b

Person: GRASP THE PYRAMID. Computer: I DON'T UNDERSTAND WHICH PYRAMID YOU MEAN. Person: FIND A BLOCK WHICH IS TALLER THAN THE ONE YOU ARE HOLDING AND PUT IT INTO THE BOX. Computer: BY "IT", I ASSUME YOU MEAN THE BLOCK WHICH IS TALLER THAN THE ONE I AM HOLDING. Computer: OK. (does it) Person: WHAT DOES THE BOX CONTAIN? Computer: THE BLUE PYRAMID AND THE BLUE BLOCK. Person: WHAT IS THE PYRAMID SUPPORTED BY? Computer: THE BOX. Person: HOW MANY BLOCKS ARE NOT IN THE BOX? Computer: FOUR OF THEM. • The promise was "It'll scale, honest..." • Planners simulated manipulating simple shapes like this:

• Even some simple natural language handling:

cisc3410-fall2010-parsons-lect01b

17

19

A dose of reality, 1966–1973:

- Techniques developed on microworlds *would not* scale.
- Implications of *complexity theory* developed in late 1960s, early 1970s began to be appreciated:
 - brute force techniques will not work.
 - works in principle does not mean works in practice.
- Lots of early programs did symbol manipulation without any real understanding of the domain they were in.

cisc3410-fall2010-parsons-lect01b

- Expert systems success stories:
 - MYCIN blood diseases in humans;
 - DENDRAL interpreting mass spectrometers;
 - R1/XCON configuring DEC VAX hardware;
 - PROSPECTOR finding promising sites for mineral deposits;
- Expert systems emphasised *knowledge representation*: rules, frames, semantic nets.
- Problems:
 - the knowledge elicitation bottleneck;
 - marrying expert system & traditional software;
 - breaking into the mainstream.

Knowledge based systems, 1969–1979:

- General purpose, brute force techniques don't work, so use *knowledge rich* solutions.
- Early 1970s saw emergence of *expert systems* as systems capable of exploiting knowledge about tightly focussed domains to solve problems normally considered the domain of experts.
- Ed Feigenbaum's knowledge principle:

[Knowledge] is power, and computers that amplify that knowledge will amplify every dimension of power

cisc3410-fall2010-parsons-lect01b

AI makes money, 1980-present

- R1 was the first commercial expert system.
- Led to a boom in expert systems companies.
 - Like an earlier dot com boom
- Most of those companies failed to deliver increased productivity for their customers.
- They went bust.
- AI suffered from all the broken promises, but didn't go away.

cisc3410-fall2010-parsons-lect01b

23

22

- Connection back to other fields.
 - Probability/statistics
 - Control theory
 - Economics
 - Operations research
- New industries spawned.
 - Data mining is machine learning.
- Low-key successes.
 - Expert systems embedded in Windows
- Increased emphasis on shared datasets, common problems, competitions.

AI and the scientific method, 1987-present

- Early AI was all about writing cool programs to demonstrate what could be done.
- About rejecting the limitations of existing fields.
- Now it is more about identifying hypotheses and empirically evaluating them.
 - I can show that my machine learning method will converge by running experiments and showing that it reliably converges.
- Or, alternatively, about proving theorems about techniques.
 - I can show that my machine learning method will converge by proving that it will do so, under reasonably assumptions.
- Distinction between *neat* and *scruffy* AI.

cisc3410-fall2010-parsons-lect01b

cisc3410-fall2010-parsons-lect01b

27

Intelligent agents, 1993–present:

- Emphasis on understanding the interaction between *agents* and *environments*.
- AI as *component*, rather than as end in itself.
 - "Useful first" paradigm Etzioni (NETBOT, US\$35m)
 - "Raisin bread" model Winston.
- More about interaction between components, emergent intelligence, and doing well enough to be useful.
- We will concentrate on this view in the class.

cisc3410-fall2010-parsons-lect01b

Large datasets, 2001-present

- Change in emphasis from *algorithm* to *data*.
 - Perhaps with enough data, we don't have to be smart to be good.
- For example, how to fill in a gap in a picture.
 - Perhaps you have a picture of your ex in front of a great landscape.
- Poll lots of similar pictures for a matching piece.
 - Moving from 10,000 images to 2,000,000 led to a big jump in performance.
- Wisdom of the crowd.

cisc3410-fall2010-parsons-lect01b

• Good enough to be useful.

• The growth of the internet makes this much easier in 2010 than it was in 1990. (Why?)

- Currently a lot of interest in mining data from social networks.
- If people are connected, they are similar in some sense.

cisc3410-fall2010-parsons-lect01b

29

31

- *environment*: physical world;
- *sensors*: eyes, ears, ...
- *effectors*: hands, legs, ...
- Software agent:
 - *environment*: (e.g.) UNIX operating system;
 - sensors: ls, ps, ...
 - *effectors*: rm, chmod, ...
- Robot:
 - *environment*: physical world;
 - sensors: sonar, camera;
 - *effectors*: wheels.

cisc3410-fall2010-parsons-lect01b

• *Ideal rational agent:*

For each percept sequence, an ideal rational agent will act to maximise its expected performance measure, on the basis of information provided by percept sequence plus any information built in to agent.

- Note that this does not preclude performing actions to *find things out*.
- More precisely, we can view an agent as a function:

 $f: P^* \to A$

38

from sequences of percepts *P* to actions *A*.

cisc3410-fall2010-parsons-lect01b

37

Simple reflex agent

• A simple agent maps percepts directly to actions:

Fully observable versus partially observable

- A *fully observable* environment is one in which the agent can obtain complete, accurate, up-to-date information about the environment's state.
- Such an environment is also called *accessible*.
- Most moderately complex environments (including, for example, the everyday physical world and the Internet) are only *partially observable*.
- Such environments are also known as *non-accessible*
- The more observable an environment is, the simpler it is to build agents to operate in it.

cisc3410-fall2010-parsons-lect01b

Episodic versus sequential

- In an *episodic* environment, the performance of an agent is dependent on a number of discrete episodes, with no link between the performance of an agent in different scenarios.
- An example of an episodic environment would be an assembly line where an agent had to spot defective parts.
- Episodic environments are simpler from the agent developer's perspective because the agent can decide what action to perform based only on the current episode — it need not reason about the interactions between this and future episodes.
- Environments that are not episodic are called either *non-episodic* or *sequential*. Here the current decision affects future decisions.
- Driving a car is sequential.

cisc3410-fall2010-parsons-lect01b

Deterministic versus non-deterministic

- A *deterministic* environment is one in which any action has a single guaranteed effect there is no uncertainty about the state that will result from performing an action.
- The physical world can to all intents and purposes be regarded as non-deterministic.
- The textbook calls non-deterministic environments *stochastic* if we quantify the non-determinism using probability theory.
- Non-deterministic environments present greater problems for the agent designer.

cisc3410-fall2010-parsons-lect01b

45

47

Static vs dynamic

- A *static* environment is one that can be assumed to remain unchanged except by the performance of actions by the agent.
- A *dynamic* environment is one that has other processes operating on it, and which hence changes in ways beyond the agent's control.
- The physical world is a highly dynamic environment.
- One reason an environment may be dynamic is the presence of other agents.
