LECTURE 2: INTELLIGENT AGENTS

An Introduction to Multiagent Systems CIS 716.5, Spring 2005

1.1 Reactivity

• If a program's environment is guaranteed to be fixed, the program need never worry about its own success or failure — program just executes blindly.

Example of fixed environment: compiler.

- The real world is not like that: things change, information is incomplete. Many (most?) interesting environments are *dynamic*.
- Software is hard to build for dynamic domains: program must take into account possibility of failure ask itself whether it is worth executing!
- A *reactive* system is one that maintains an ongoing interaction with its environment, and responds to changes that occur in it (in time for the response to be useful).

• Trivial (non-interesting) agents:

- thermostat;

Lecture 2

- UNIX daemon (e.g., biff).
- An *intelligent* agent is a computer system capable of *flexible* autonomous action in some environment.
 - By *flexible*, we mean:
 - reactive;
 - pro-active;
 - social.

 Main differences: agents are autonomous: agents are body stronger notion of autonomy than objects, and in particular, they decide for themselves whether or not to perform an action on request from another agent; agents are smart: capable of flexible (reactive, pro-active, social) behavior, and the standard object model has nothing to say about such types of behavior; agents are active: a multi-agent system is inherently multi-threaded, in that each agent is assumed to have at least one thread of active control. Wooldridge, used by permission (M. J. Wooldridge, used by permission 			_

argued that there are occasions when the intentional appropriate:

fs, free will, intentions, consciousness, abilities, or wants to a mate when such an ascription expresses the same information ne that it expresses about a person. It is useful when the us understand the structure of the machine, its past or future w to repair or improve it. It is perhaps never logically required , but expressing reasonably briefly what is actually known about nachine in a particular situation may require mental qualities or bhic to them. Theories of belief, knowledge and wanting can be nachines in a simpler setting than for humans, and later applied iption of mental qualities is most straightforward for machines of such as thermostats and computer operating systems, but is en applied to entities whose structure is incompletely known'.

An Introduction to Multiagent Systems

er seems to be that while the intentional stance is consistent.

bes not buy us anything, since we essentially and the mechanism sufficiently to have a simpler, mechanistic description of its behaviour. (Yoav Shoham)

- Put crudely, the more we know about a system, the less we need to rely on animistic, intentional explanations of its behaviour.
- But with very complex systems, a mechanistic, explanation of its behaviour may not be practicable.
- As computer systems become ever more complex, we need more powerful abstractions and metaphors to explain their operation - low level explanations become impractical. The intentional stance is such an abstraction.

ecture 2 An Introduction to Multiagent System	s
11 Summary	
 This lecture has looked in detail at what constitutes an intelligent agent. 	
 We looked at the properties of an intelligent agent and the properties of the environents in which it may operate. 	
• We introduced the intentional stance and discussed its use.	
 In the next lecture, we will start to look at hoe one might program an agent. 	ı
 We looked at abstract architectures for agents of different kinds; and 	
 Finally we dicussed the notion of an optimal agent.
